#### QUESTION

# IS STAR FORMATION RAPID AND DYNAMIC OR SLOW AND QUASI STATIC?

distributions of stellar ages in young stellar clusters give us an

answer but ... are stellar ages accurate and precise enough?

### WHAT THE LUMINOSITY SPREAD IN THE HR DIAGRAM TELLS US?

- Palla & Stahler (2000): accelerating SF
- Hartmann (2001, 2003): uncertainties & measurement errors

- Reggiani+11: little (1.5-3.5Myr) age spread in ONC

- Kudryavtseva+12: instantaneous SF in NGC3603

Correnti12: slow SF in NGC 3603

Preibisch (2012): uncertainties, misinterpretation of accelerating SF, projection effects

- Beccari+17: multiple sequence in the color-magnitudo diagram in ONC

#### **BASIC INFORMATION**

# NGC 6530 IN THE LAGOON

- distance: 1250 pc (Prisinzano+05) confirmed by Gaia population: >2000 members (Damiani+19) literature age:1-10 Myr reddening: E(B-V)=0.27
  - $\checkmark$  cluster associated to the Lagoon Nebula (M8)
  - vevidence of asymmetric expansion: ionized and neutral gas shells related to NGC6530 and OB stars (Damiani+18,Wright+19)
     hints of triggered star formation (SF) in molecular gas compressed by ionization front (Tothill+08)

## Gaia-ESO Survey (GES)

(Gilmore et al. 2012, Randich et al. 2017) VLT/FLAMES spectra for **2077 targets** in the NGC6530 field

iDR5 EW(Li) - FWZI (Hα) radial and rotational velocities T<sub>eff</sub> - γ gravity index (Damiani+14)

## Other data

- opt. photometry ESO-WFI (V, I) (Prisinzano+05) & VPHAS+ (Kalari+15)
- IR photometry from 2MASS and Spitzer
- Chandra ACIS-I X-ray detections
- Gaia DR2 kinematics and parallaxes

# CLUSTER

# MEMBERSHIP

- Radial Velocities

- γ index
- Gaia proper motions
- Gaia parallaxes
- NIR excess
- (Kumar & Anandarao (2010 Feigelson+2013 Broos+13)

inclusive approach652 members confirmed9 probabile members

new definition: 333 CTTSe: accretors OR disk 328 WTTSp: no accretion nor disk

(b)

## REDDENING LAW TOWARDS NGC6530

proven to be non-standard using independently spectroscopy and photometry

### compatible with R=5.0

## INTRINSIC COLOR-MAGNITUDE AND HR DIAGRAMS FOR WTTSp & CTTSe

bilinear interpolation (Tognelli+11, Randich+17) ages for 147 WTTSp & 240 CTTSe

-Ages: Pisa isochrone

HR diagram of WTTSp is not affected by variability accretion

- Overall similar luminosity spread in both CTTSe and WTTSp

# LOG-NORMAL AGE DISTRIBUTION

mean log age	dispersion	sample
[dex]	[dex]	
5.84	0.36	all members
5.92	0.35	WTTSp
5.81	0.37	CTTSe

- no substantial difference in age spread between WTTSp and CTTSe
- but ... is this age spread due to errors?

in the low mass range

( $T_{eff}$ <5500 K

 $0.24 < M/M_{\odot} < 2.80)$ 

## ERRORS ON STELLAR AGES

 $\sigma$ (V-I)<sub>0</sub> depends on T<sub>eff</sub> errors

 $\sigma(V)_0$  depends on - photometric errors on V and I

- error on spectroscopic  $\,T_{\rm eff}$
- ph. variability: extinction included in A(V)

accretion bursts (Gullbring+98, Baraffe+09)

- hot spots<sup>(Cody+14, Stauffer+16)</sup>
- cool spots (Cody+14, Stauffer+16)
- distance error: systematic does not affect the spread random component is negligible
- binarity: systematic bias mimicking younger ages

## MONTECARLO SIMULATIONS FOR EACH STAR

- three sets of 1000 values of  $T_{eff}$ , V and I, normally distributed, with dispersions equal to  $\sigma T_{eff}$ ,  $\sigma V$  and  $\sigma I$  of the star
- one set of 1000  $\Delta$ I values with mean  $\langle \Delta I \rangle = 0.11$  and  $\sigma(\Delta I) = 0.03$  (Henderson & Stassun, 2012)
- one set of 1000 dI/dV values with mean  $\langle dI/dV \rangle = 0.67$  and  $\sigma(dI/dV) = 0.13$  (Herbst+94)

added the simulated errors to  $V_0$  and  $(V-I)_0$  and derived

1000 values of stellar ages for each star -> 0.09 dex (random error)

**binarity:** 1000  $\Delta$  log *L* values between 0.05 and 0.3 (Hartmann, 2001) –>

dV added to a coeval 1Myr population -> 0.10 dex (systematic error)

TOTAL ISOCHRONAL AGE UNCERTAINTY vs. OBSERVED SPREAD 0.13 dex < 0.36 dex EVIDENCE OF A SMALL BUT REAL AGE SPREAD!

## **EVIDENCE OF GRAVITY SPREAD!**

# **SPATIAL DISTRIBUTIONS**

# YOUNGEST CTTSe vs. OLDEST CTTSe and WTTSp

- youngest CTTSe: two radial concentrations (NGC6530 & 9Sgr/Her36)
- youngest CTTSe: bow-shape from Her36 to M8E-IR
- other members:
  sparse distribution
- youngest CTTSe: proper motion pattern

- observed age spread is larger than age error spread, evidence of a real age spread
- spectroscopic gravity spread supporting age spread
- peculiar spatial distribution supporting age spread
- kinematics difference evidence of two different SF events triggered and pushed by two different ionizing fronts. Consistent with previous scenarios suggested in the literature
