Disk evolution

Stars are born surrounded by disks Disks are 99% gas, 1% solids = dust

Disks are accreting
Disks evolve from gas-rich primordial to dust-rich
debris disks – planetary systems in few Myrs

Evidence of evolution

Decrease with age of

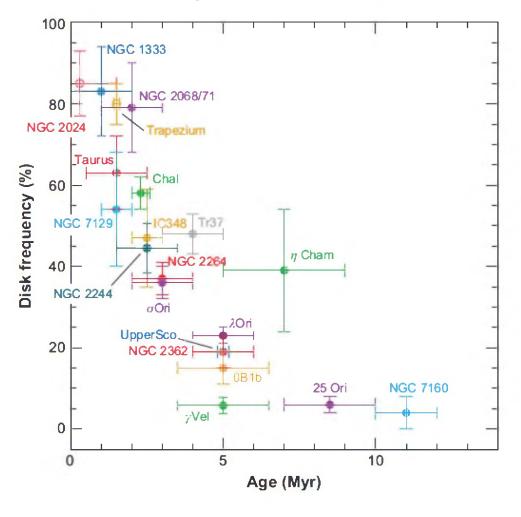

Disk frequency

Mass accretion rate

IR excess

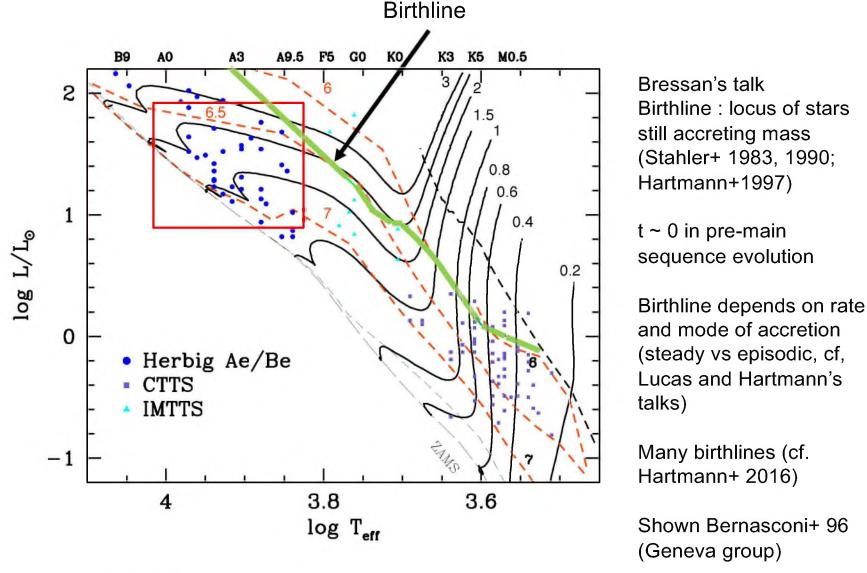

Structure/Planets

Disk frequency decreases with age of population

From Spitzer photometry => inner disk

Age determination: effects of birthline

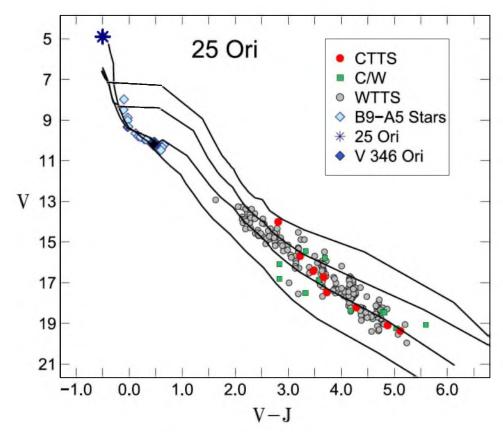

With this birthline:
Actual ages including t ~ 0 at birthline: ``lsochronal ages" – 3 Myr:

Use isochronal ages of low mass stars in population (less affected, birthline ~ D main sequence)

Results from the CIDA variability survey of Orion, Briceno+ 2019

Disk evolution

Hernandez+ 2005: Frequency of Herbig Ae/Bes in populations covering range of ages

Ori OB1bc Upper Sco Per Ob2 Ori OB1a Lac OB1

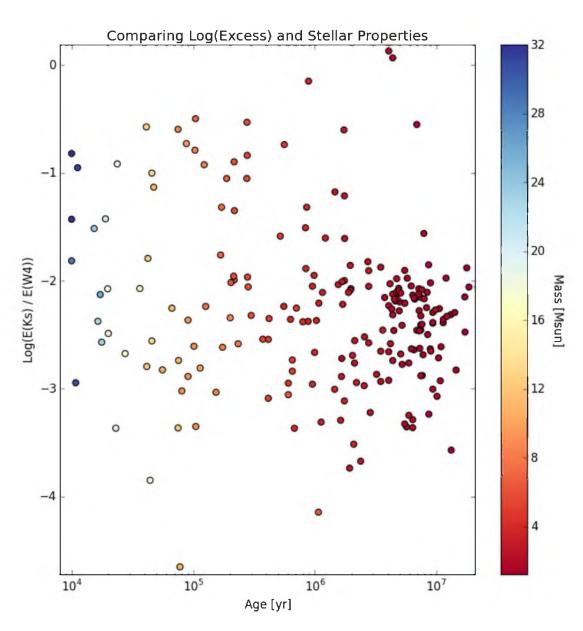

Disks around intermediate mass stars evolve much faster

(see also Yao+2018)

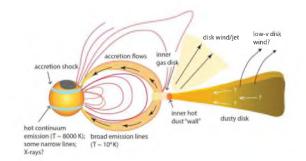

Solid: Intermediate mass stars

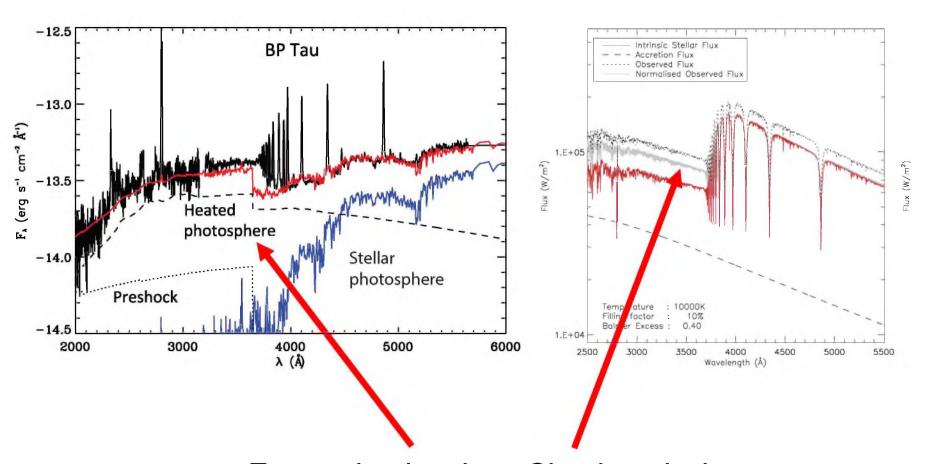

Open: Low mass stars

Birthline effects?

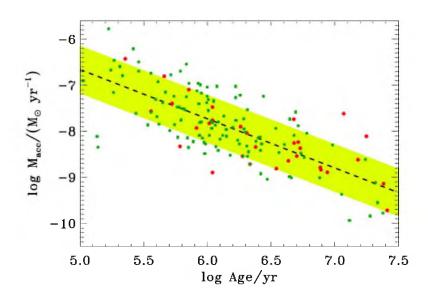

Accretion luminosity from shock emission

Excess luminosity = Shock emission $\sim L_{acc} = G M_* Mdot/R_*$

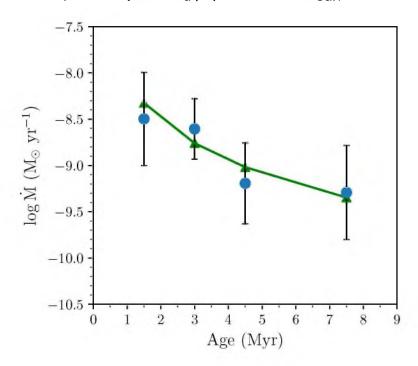

Evolution of the mass accretion rate

Individual determinations of Mdot and age (compilation and references in Hartmann+ 2016)

Group populations of similar age (from isochrone fitting of low mass stars) in bins Medians and Quartiles

Consistent with viscous evolution $R_1 = 10 \text{ pc}$, $M_d(0) = 0.06 \text{ M}_{sun}$, $\alpha = 0.01 \text{ m}_{sun}$

Manzo-Martinez+

Viscous Evolution

Disk expands as it accretes mass onto star to conserve J

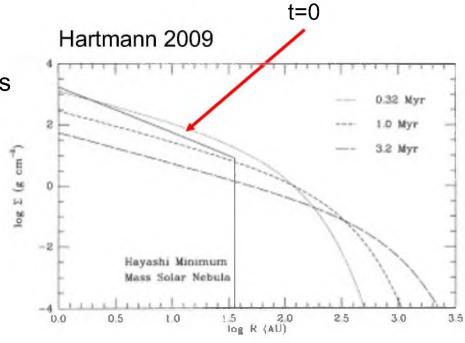

Surface density Σ decreases, Mass accretion rate and mass fall (lost to the star)

Evolution in viscous time scale

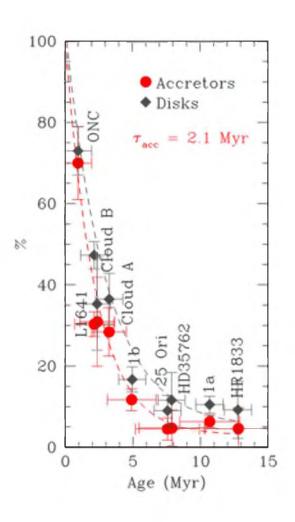

$$t_v \sim 8 \times 10^4 \left(\frac{R}{10au}\right) \left(\frac{\alpha}{0.01}\right)^{-1} \left(\frac{M_*}{0.5M_{\odot}}\right)^{1/2} \text{ yrs}$$

Disk may not be steady:

Dead zone
Mass into forming planets
Still constrains mass onto
star

Accretors frequency also decreases with age of population

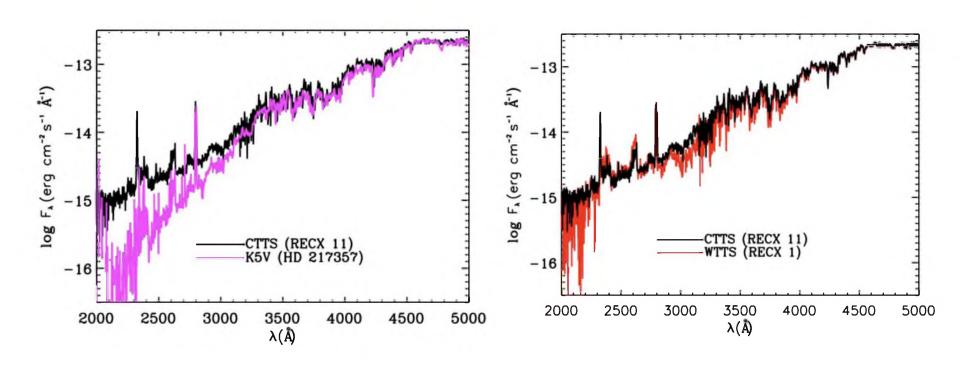

Fewer accretors as age increases
Cannot be explained by viscous evolution

Decrease comparable to inner disk frequency But fewer accretors than inner disks at old ages

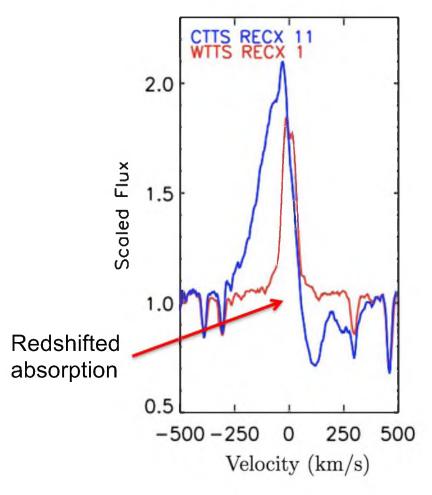

Search for low accretors:
About ~ 25+ % of "WTTS" with detectable IR excess are accreting!
Low rates (TBD)
(Thanathibodee+ 2019)

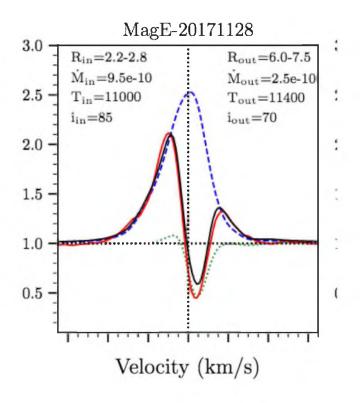

The danger of determining **low** Mdots from UV excess

WTTS = Non accreting stars have strong chromospheres Cannot measure rates < few x 10^{-10} M_{sun}/yr from U excesses

Use emission lines to check and measure accretion – H α most common

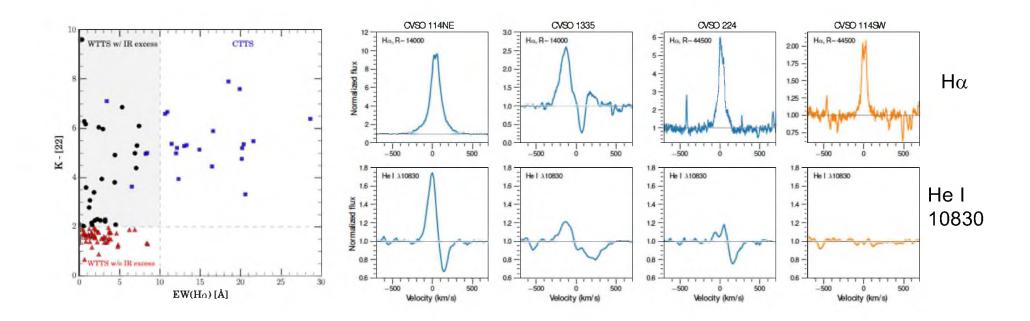

Thanathibodee+ 2019

Lowest accretors are hiding!

Look among WTTS with IR excess Look for redshifted absorption at He I 10830, best indicator!

Evolution of disk NIR flux excess

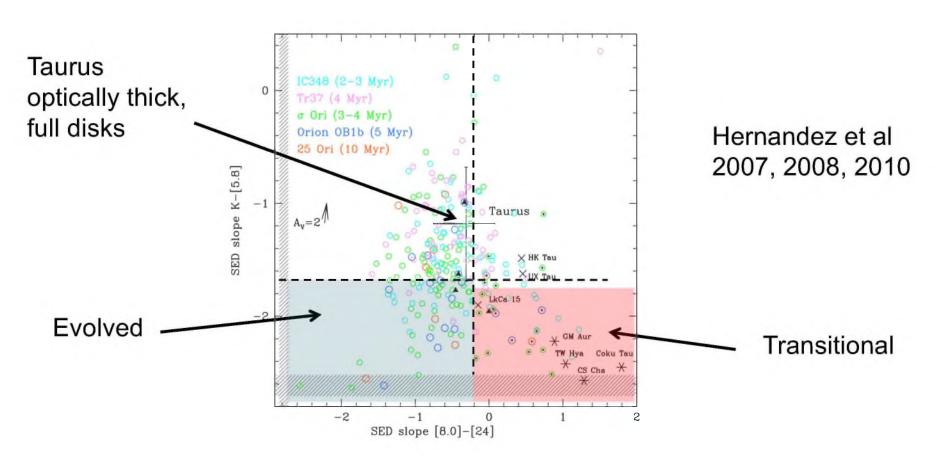

Comparing to optically thick disks: Taurus

Evolved (anemic, homologously depleted) disks:

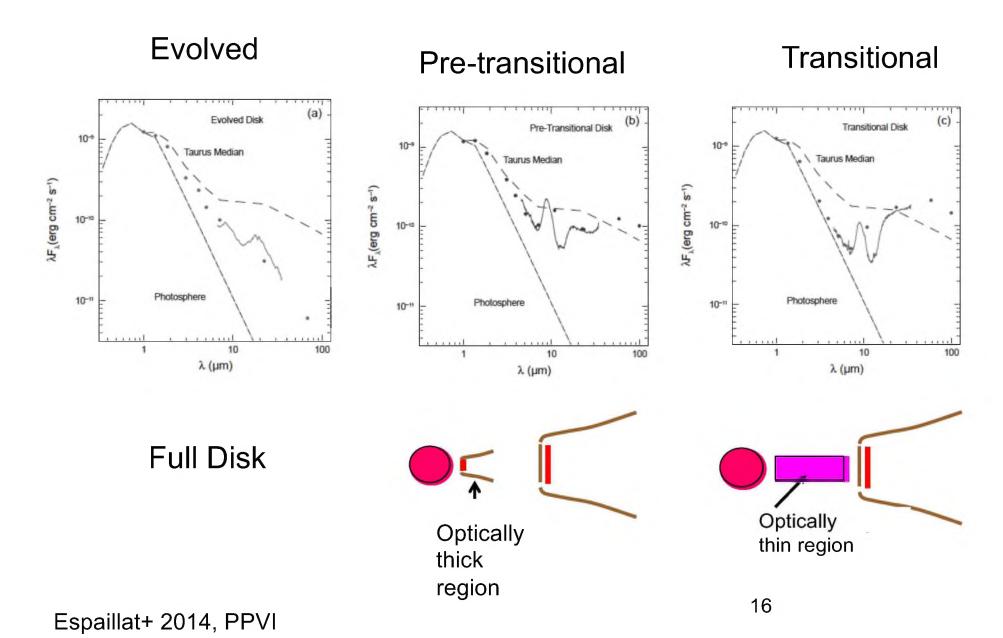

flux decreases at all bands

Transitional disks:

near IR close to photosphere mid-far IR comparable or higher than Taurus

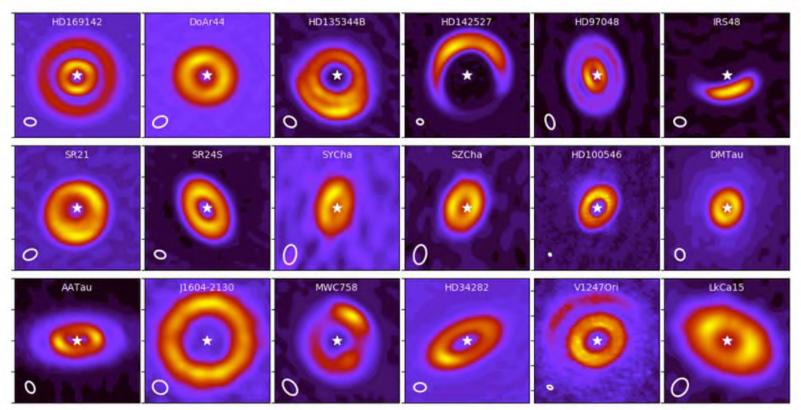

Representative SEDs

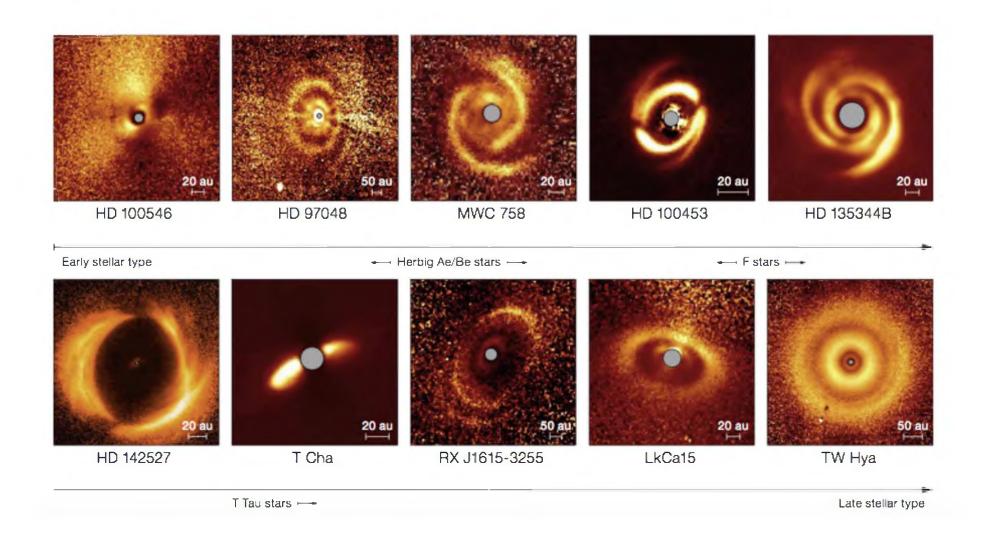

ALMA images of transitional and pre-transitional disks

Cavities of ~ few x 10 au's

Gallery of ALMA continuum images of transition disks (credits Nienke van der Marel).

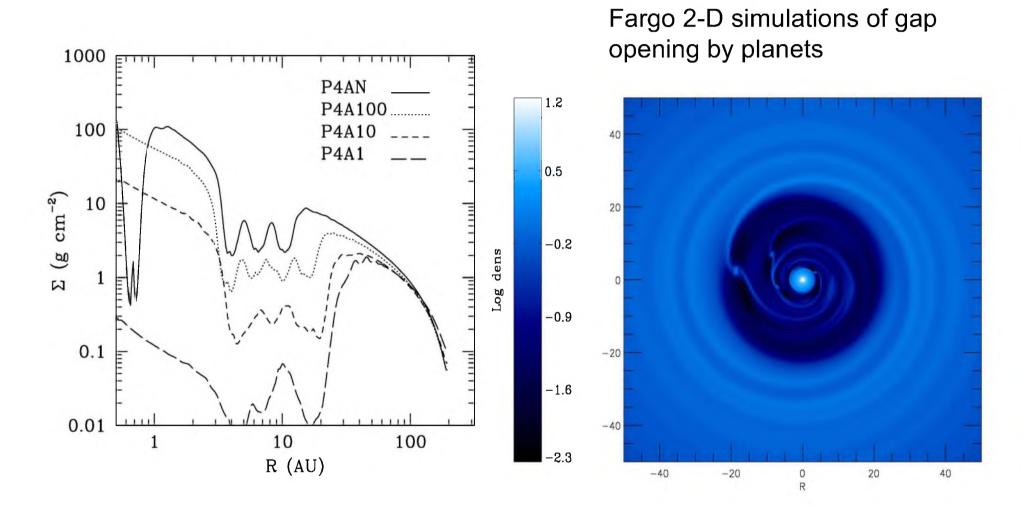

Images in near-IR

Structure in "Full" disks

The ALMA revolution!

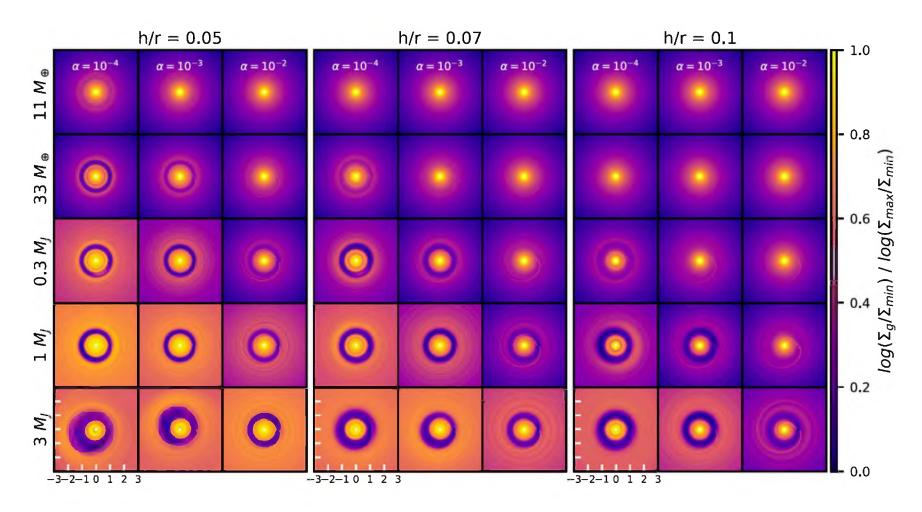

How does structure fit into global evidence of disk evolution?

Disk evolution: "Full" disks! Not TD

$$L_{\nu} = 4\pi d^2 \nu F_{\nu}$$

Structure: planet formation

Parameters: Σ_0 , α , h/r, M_p/M_* , dust size distribution Deeper gaps with more massive planets, lower α

Zhang,S, Zhu+ 2019

Application: AS 209

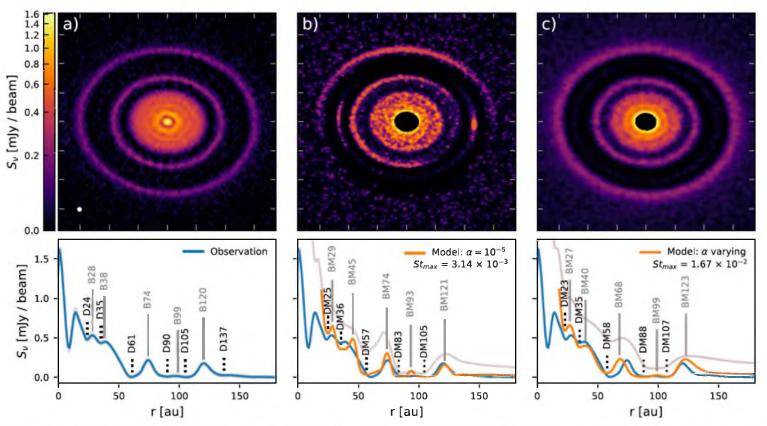

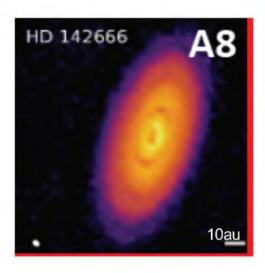

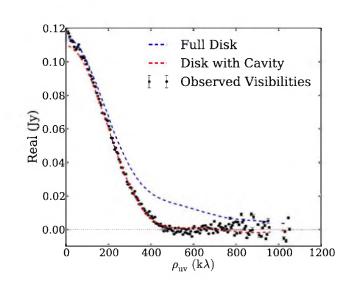

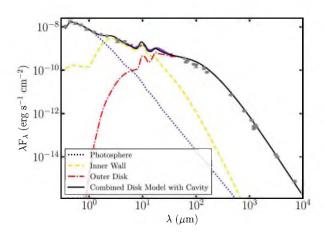

Figure 19. Top panels: (a) the observation image of AS 209 (see Guzman et al. 2018, Huang et al. 2018a). The distance between two ticks on the axes is 40 au. (b) The synthetic image from the simulation with a single planet $(M_p/M_*=0.1\,M_J/M_\odot)$ at 99 au in a $\alpha=10^{-5}$, $\Sigma_{g,0}=15$ g cm⁻², $s_{max}=0.3$ mm, and p=-3.5 disk at 2000 orbits (~2 Myr). (c) The synthetic image from the simulation with a single planet $(M_p/M_*=0.1\,M_J/M_\odot)$ at 99 au in a varying α , $\Sigma_{g,0}=6.4$ g cm⁻², $n(s) \propto s^{-3.5}$, and $s_{max}=0.68$ mm disk at 1350 orbits (~1.35 Myr). Bottom panels: the azimuthally averaged intensity profiles. Panel (a) is the profile from the observation, and (b) and (c) are the profiles from the simulations above. The "DM" and "BM" stand for dark annulus and bright ring in the model, respectively; the digits coming after mark the position in astronomical units. The gas density profiles of two models are overplotted on the bottom panels in gray in arbitrary units.

Dust evolution

Rubinstein+2019

 R_{cav} ~ 16 au Substantial amount of small grains in inner disk

~ 10% of large grains

**
$$M_d \sim 0.05 M_{sun} \sim 52 M_J$$

$$Mdot \sim 10^{-8} - 10^{-7} M_{sun}/yr$$

$$M_p \sim 0.1 - 0.3 M_J \text{ (Zhang+ 2019)}$$

Long term dust evolution

Once a planet form in disk, what is the subsequent evolution of the disk?

Of these disks with remaining small dust in inner disk, what follows?

Why is dust remaining in some and not others?

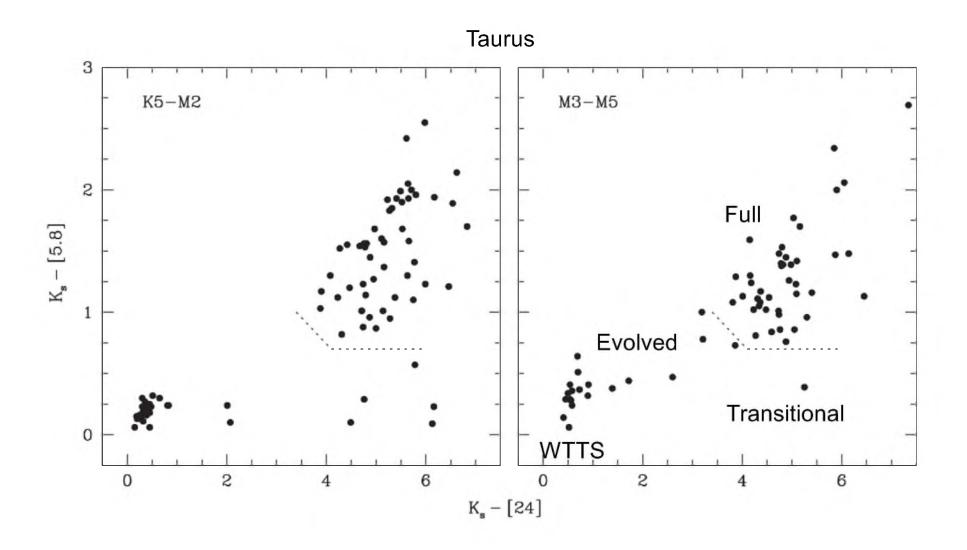

How is the overall disk evolution affected by formation of planets?

Bias towards bright and larger disks

Disks fainter as they age – more difficult to get high resolution observations

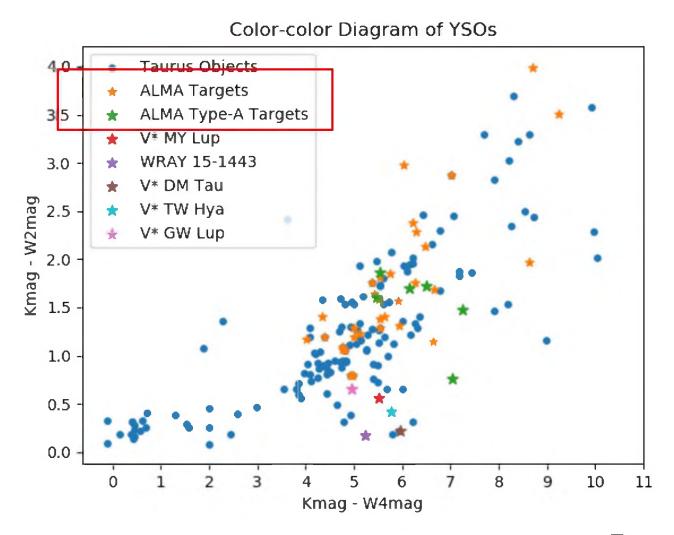

Have to look at colors

Low mass stars

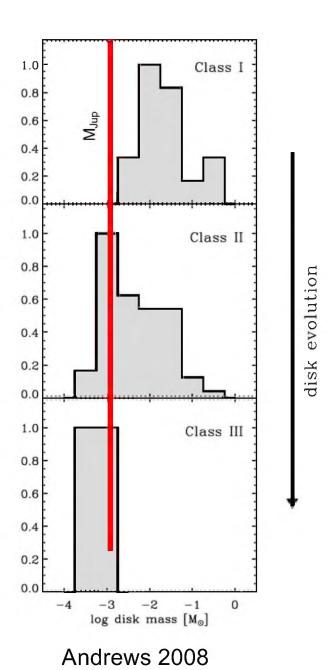

Colors of ALMA disks

Disks with structure are not distinguishable from the general population of disks in color-color diagrams

Taurus: Esplin+2019

Disk Masses

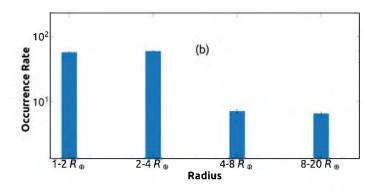

Do planets affect disk evolution? Mass of disk/Mass of planets

Gas mass – uncertain, depends on indicator CO low, Williams+ 2014 HD Bergin+2013, McClure+2016

Most exoplanetary system do not have Jupiter mass planets

Some systems w multiple giants multiplicity not precisely known

Narang+2018

Evolution of IR excess

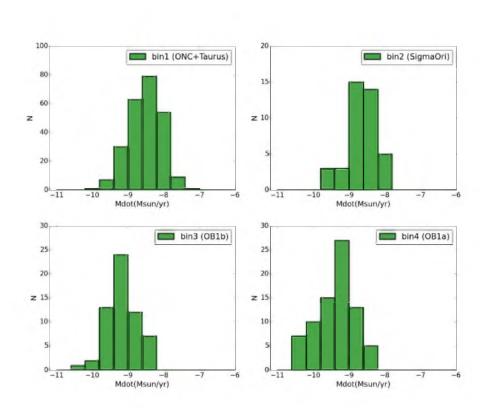

Assuming the planets do not affect disk evolution Study how IR excess and accretion changes with time Large set of populations of different ages

INNER DISK EVOLUTION

settling

Effects of Photoevaporation

Alexander et al. 2006

High energy radiation photoevaporates disk

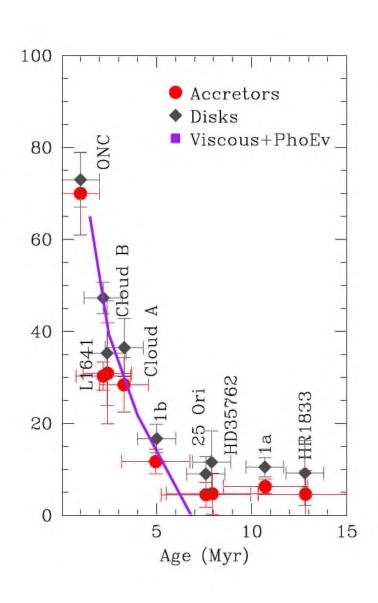

$$c_s \sim V_{esc}$$

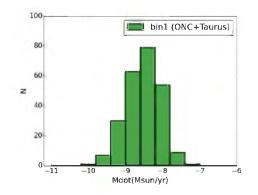

When mass accretion rate (decreasing by viscous evolution) ~ mass loss rate, no mass reaches inner disk, depleted in viscous time scale of inner disk (~ 10⁵ yrs or less)

After hole forms, direct photoevaporation of edge, inner cleared region grows fast, no inner disk left

Gorti, Pascucci, Clark, Owens, Ercolano, Alexander

Photoevaporation determines frequency

Distribution of Mdot at 2 Myr

Manzo-Martinez+2019

Let Mdot(t₀) distribution evolve viscously

If/when Mdot(t) falls below Mdot_{lim} disk photoevaporates quickly

$$Mdot_{lim} = 3 \times 10^{-10} M_{sun}/yr$$

$$\alpha = 0.01$$

Data from Briceno+2019

Conclusions

Viscous evolution and photoevaporation are the main drivers of evolution for the gas in protoplanetary disk

large spread at given age, initial conditions? can photoevaporation explains dependence of disk lifetime with stellar mass?

The decrease of disk and accretors frequencies are consistent with a low mass rate in the photoevaporative wind

Solids seems to evolve separately from gas, evolution gives rise to structure, planets

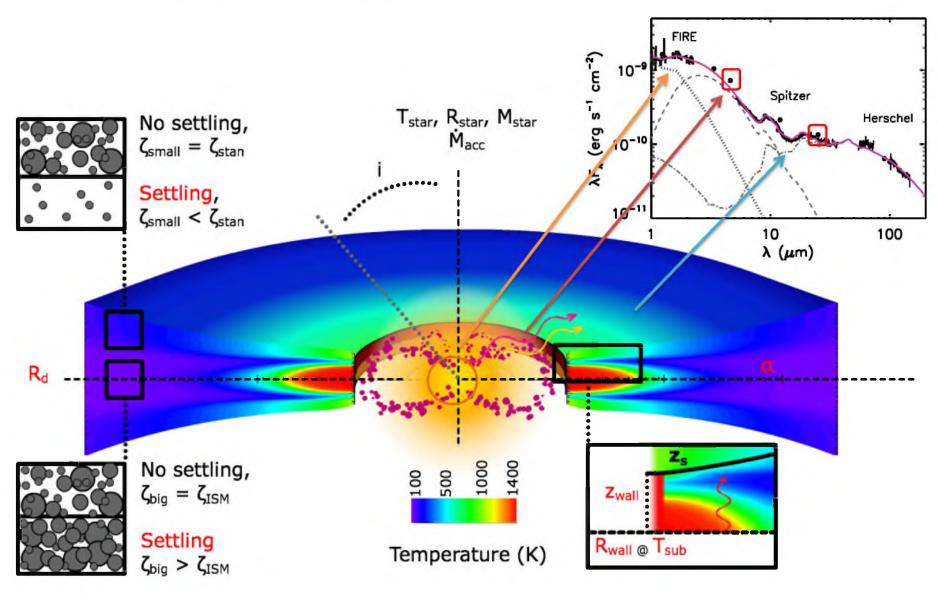

Planets do not seem to influence much the overall disk evolution needs to be explored in more detail

Caution with ages – birthline effects

Dust evolution indicated by two parameters:

 $z_{\text{wall}} \sim \text{height of disk at dust destruction radius, DCE J} - [4.5]$

 ϵ = dust2gas mass ratio of grains in upper levels = $\zeta_{small}/\zeta_{ISM}$, DCE J – [24]

D'Alessio+(2006). Art: Melissa McClure

Effects of dust settling in SED

Less opacity in upper layers, less heating, lower flux

Dullemond & Dominik 2004; D' Alessio+ 2006
